

## A Digression: A Bad Proof

Prove  $\log(x/y) = \log(x) - \log(y)$

**Proof:**

$$\begin{aligned} \log(x/y) &= \log(x) - \log(y) \\ \log(x) + \log(1/y) &= \log(x) - \log(y) \\ \log(x) + \log(y^{-1}) &= \log(x) - \log(y) \\ \log(x) - \log(y) &= \log(x) - \log(y) \end{aligned}$$

What's wrong?

- You need to connect the statements (using  $\Leftrightarrow$ , for example)

1

## Inductive Definitions

**Example:** Define  $\sum_{k=1}^n a_k$  inductively (i.e., by induction on  $n$ ):

- $\sum_{k=1}^1 a_k = a_1$
- $\sum_{k=1}^{n+1} a_k = \sum_{k=1}^n a_k + a_{n+1}$

The inductive definition avoids the use of  $\dots$ , and thus is less ambiguous.

**Example:** An inductive definition of  $n!$ :

- $1! = 1$
- $(n+1)! = (n+1)n!$

Could even start with  $0! = 1$ .

2

## Inductive Definitions of Sets

A *palindrome* is an expression that reads the same backwards and forwards:

- Madam I'm Adam
- Able was I ere I saw Elba

What is the set of palindromes over  $\{a, b, c, d\}$ ? Two approaches:

1. The smallest set  $P$  such that
  - (a)  $P$  contains  $a, b, c, d, aa, bb, cc, dd$
  - (b) if  $x$  is in  $P$ , then so is  $axa, bxb, cxc, dxd$
2. Define  $P_n$ , the palindromes of length  $n$ , inductively:
  - $P_1 = \{a, b, c, d\}$
  - $P_2 = \{aa, bb, cc, dd\}$
  - $P_{n+1} = \{axa, bxb, cxc, dxd \mid x \in P_{n-1}\}, n \geq 2$

Let  $P' = \cup_n P_n$ .

3

**Theorem:**  $P = P'$ . (The two approaches define the same set.)

**Proof:** Show  $P \subseteq P'$  and  $P' \subseteq P$ .

To see that  $P \subseteq P'$ , it suffices to show that

- (a)  $P'$  contains  $a, b, c, d, aa, bb, cc, dd$
- (b) if  $x$  is in  $P'$ , then so is  $axa, bxb, cxc, dxd$  (since  $P$  is the least set with these properties).

Clearly  $P_1 \cup P_2$  satisfies (1), so  $P'$  does. And if  $x \in P'$ , then  $x \in P_n$  for some  $n$ , in which case  $axa, bxb, cxc, dxd$  are all in  $P_{n+2}$  and hence in  $P'$ . Thus,  $P \subseteq P'$ .

To see that  $P' \subseteq P$ , we prove by strong induction that  $P_n \subseteq P$  for all  $n$ . Let  $P(n)$  be the statement that  $P_n \subseteq P$ .

**Basis:**  $P_1, P_2 \subseteq P$ : Obvious.

Suppose  $P_1, \dots, P_n \subseteq P$ . If  $n \geq 2$ , the fact that  $P_{n+1} \subseteq P$  follows immediately from (b). (Actually, all we need is the fact that  $P_{n-1} \subseteq P$ , which follows from the (strong) induction hypothesis.)

Thus,  $P' = \cup_n P_n \subseteq P$ .

4

Recall that the set of palindromes is the smallest set  $P$  such that

- (a)  $P$  contains  $a, b, c, d, aa, bb, cc, dd$
- (b) if  $x$  is in  $P$ , then so is  $axa, bxb, cxc, and dxd$

“Smallest” is not in terms of cardinality.

- $P$  is guaranteed to be infinite

“Smallest” is in terms of the subset relation.

Here’s a set that satisfies (a) and (b) and isn’t the smallest:

Define  $Q_n$  inductively:

- $Q_1 = \{a, b, c, d\}$
- $Q_2 = \{aa, bb, cc, dd, ab\}$
- $Q_{n+1} = \{axa, bxb, cxc, dxd \mid x \in Q_{n-1}\}, n \geq 2$

Let  $Q = \cup_n Q_n$ .

It’s easy to see that  $Q$  satisfies (a) and (b), but it isn’t the smallest set to do so.

## Just a Reminder

(from your friendly sponsor)

What’s (usually) a key step in proving a property of an algorithm:

Find a loop invariant!

- State clearly what the invariant is
- Prove that it holds (often by induction, since the invariant says “On the  $n$ th iteration of the loop, property  $P(n)$  holds”)

## Graphs and Trees

Graphs and trees come up everywhere. We saw an example in Chapter 0 of a *precedence graph*. Here’s another example of where graphs come in handy:

A farmer is bringing a wolf, a cabbage, and a goat to market. They need to cross a river in a boat which can accommodate only two things, including the farmer. Moreover:

- the farmer can’t leave the wolf alone with the goat
- the farmer can’t leave the goat alone with the cabbage

How should he cross the river?

Getting a good representation is the key.

What are the allowable configurations?

- A configuration looks like  $(X, Y)$ , where  $X, Y \subseteq \{W, C, F, G\}, Y = \bar{X}$
- Can have  $X$  on the initial side of the river,  $Y$  on the other

$(WCFG, \emptyset)$	$(\emptyset, WCFG)$
$(WCF, G)$	$(G, WCF)$
$(WGF, C)$	$(C, WGF)$
$(CGF, W)$	$(FG, WC)$
$(WC, FG)$	$(W, CFG)$

- Disallowed configurations:  $(WG, FC), (GC, FW), (FC, WG), (FW, GC)$
- Initial configuration:  $(WCFG, \emptyset)$ .

Use a graph to represent when we can get from one configuration to another.

## Other Examples

### Niche graphs (Ecology):

- The vertices are species
- Two vertices are connected by an edge if they compete (use the same food resources, etc.)

Niche graphs give a visual representation of competitiveness.

### Influence Graphs

- The vertices are people
- There is an edge from  $a$  to  $b$  if  $a$  influences  $b$

Influence graphs give a visual representation of power structure.

There are lots of other examples in all fields ...

9

## Directed Graphs

Note that  $\{v, u\}$  and  $\{u, v\}$  represent the same edge.

In a *directed graph* (*digraph*), the order matters. We denote an edge as  $(v, v')$  rather than  $\{v, v'\}$ . We can identify an undirected graph with the directed graph that has edges  $(v, v')$  and  $(v', v)$  for every edge  $\{v, v'\}$  in the undirected graph.

Two vertices  $v$  and  $v'$  are *adjacent* if there is an edge between them, i.e.,  $\{v, v'\} \in E$  in the undirected case,  $(v, v') \in E$  or  $(v', v) \in E$  in the directed case.

11

## Terminology and Notation

A *graph*  $G$  is a pair  $(V, E)$ , where  $V$  is a set of *vertices* or *nodes* and  $E$  is a set of *edges* or *branches*; an edge is a set  $\{v, v'\}$  of two not necessarily distinct vertices (i.e.,  $v, v' \in V$ ).

- We sometimes write  $G(V, E)$  instead of  $G$
- If  $V = \emptyset$ , then  $E = \emptyset$ , and  $G$  is called the *null graph*.

We usually represent a graph pictorially.

- A vertex with no edges incident to it is said to be *isolated*
- If  $\{v\} \in E$  (the book writes  $\{v, v\}$ ), then there is a *loop* at  $v$
- $G'(V', E')$  is a *subgraph* of  $G(V, E)$  if  $V' \subseteq V$  and  $E' \subseteq E$ .

10

## Representing Relations Graphically

Given a relation  $R$  on  $S \times T$ , we can represent it by the directed graph  $G(V, E)$ , where

- $V = S \cup T$  and
- $E = \{(s, t) : (s, t) \in R\}$

**Example:** Represent the  $<$  relation on  $\{1, 2, 3, 4\}$  graphically.

How does the graphical representation show that a graph is

- reflexive?
- symmetric?
- transitive?

12

## Multigraphs

In a *multigraph*, there may be several edges between two vertices.

- There may be several roads between two towns.
- There may be several transformations that can change you from one configuration to another
  - This is particularly important in graphs where edges are labeled

Formally, a multigraph  $G(V, E)$  consists of a set  $V$  of vertices and a *multiset*  $E$  of edges

- The same edge can be in more than once

In this course, all graphs are *simple graphs* (not multigraphs) unless explicitly stated otherwise.

- Most of the results generalize to multigraphs

13

**Theorem:** Given a graph  $G(V, E)$ ,

$$2|E| = \sum_{v \in V} \deg(v)$$

**Proof:** For a directed graph: each edge contributes once to the indegree of some vertex, and once to the outdegree of some vertex. Thus  $|E| = \text{sum of the indegrees} = \text{sum of the outdegrees}$ .

Same argument for an undirected graph without loops. We need to double-count the loops to make this right in general.

15

## Degree

In a directed graph  $G(V, E)$ , the *indegree* of a vertex  $v$  is the number of edges coming into it

- $\text{indegree}(v) = |\{v' : (v', v) \in E\}|$

The *outdegree* of  $v$  is the number of edges going out of it:

- $\text{outdegree}(v) = |\{v' : (v, v') \in E\}|$

The *degree* of  $v$ , denoted  $\deg(v)$ , is the sum of the indegree and outdegree.

For an undirected graph, it doesn't make sense to talk about indegree and outdegree. The degree of a vertex is the sum of the edges incident to the vertex, except that we double-count all self-loops.

- Why? Because things work out better that way

14

## Handshaking Theorem

**Theorem:** The number of people who shake hands with an odd number of people at a party must be even.

**Proof:** Construct a graph, whose vertices are people at the party, with an edge between two people if they shake hands. The number of people person  $p$  shakes hands with is  $\deg(p)$ . Split the set of all people at the party into two subsets:

- $A$  = those that shake hands with an even number of people
- $B$  = those that shake hands with an odd number of people

$$\sum_p \deg(p) = \sum_{p \in A} \deg(p) + \sum_{p \in B} \deg(p)$$

- We know that  $\sum_p \deg(p) = 2|E|$  is even.
- $\sum_{p \in A} \deg(p)$  is even, because for each  $p \in A$ ,  $\deg(p)$  is even.
- Therefore,  $\sum_{p \in B} \deg(p)$  is even.
- Therefore  $|B|$  is even (because for each  $p \in B$ ,  $\deg(p)$  is odd, and if  $|B|$  were odd, then  $\sum_{p \in B} \deg(p)$  would be odd).

16

## Paths

Given a graph  $G(V, E)$ .

- A *path* in  $G$  is a sequence of vertices  $(v_0, \dots, v_n)$  such that  $\{v_i, v_{i+1}\} \in E$  ( $(v_i, v_{i+1})$  in the directed case).
- If  $v_0 = v_n$ , the path is a *cycle*
- An *Eulerian* path/cycle is a path/cycle that traverses every every edge in  $E$  exactly once
- A *Hamiltonian* path/cycle is a path/cycle that passes through each vertex in  $V$  exactly once.
- A graph with no cycles is said to be *acyclic*

17

## Trees

A *tree* is a digraph such that

- (a) with edge directions removed, it is connected and acyclic
- (b) every vertex but one, the *root*, has indegree 1
- (c) the root has indegree 0

Trees come up everywhere:

- when analyzing games
- representing family relationships

19

## Connectivity

- An undirected graph is *connected* if there is for all vertices  $u, v$ , ( $u \neq v$ ) there is a path from  $u$  to  $v$ .
- A digraph is *strongly connected* if for all vertices  $u, v$  ( $u \neq v$ ) there is a path from  $u$  to  $v$  and from  $v$  to  $u$ .
- If a digraph is *weakly connected* if, for every pair  $u, v$ , there is an edge from  $u$  to  $v$  or an edge from  $v$  to  $u$ .
- A *connected component* of an (undirected) graph  $G$  is a connected subgraph  $G'$  which is not the subgraph of any other connected subgraph of  $G$ .

**Example:** We want the graph describing the interconnection network in a parallel computer:

- the vertices are processors
- there is an edge between two nodes if there is a direct link between them.
  - if links are one-way links, then the graph is directed

We typically want this graph to be connected.

18

## Bipartite Graphs

A graph  $G(V, E)$  is *bipartite* if we can partition  $V$  into disjoint sets  $V_1$  and  $V_2$  such that all the edges in  $E$  joins a vertex in  $V_1$  to one in  $V_2$ .

**Example:** Suppose we want to represent the “is or has been married to” relation on people. Can partition the set  $V$  of people into males ( $V_1$ ) and females ( $V_2$ ). Edges join two people who are or have been married.

20

## Complete Graphs and Cliques

- An undirected graph  $G(V, E)$  is *complete* if it has no loops and for all vertices  $u, v$  ( $u \neq v$ ),  $\{u, v\} \in E$ .
  - How many edges are there in a complete graph with  $n$  vertices?

A complete subgraph of a graph is called a *clique*

- The *clique number* of  $G$  is the size of the largest clique in  $G$ .

## Characterizing Bipartite Graphs

**Theorem:**  $G$  is bipartite iff  $G$  has no odd-length cycles.

**Proof:** It's pretty easy to see that if a graph has an odd-length cycle then it can't be bipartite. (Suppose that you can partition the vertices into two sets  $V_1$  and  $V_2$  as required for bipartite and there is an odd length cycle  $(x_0, x_1, \dots, x_{2k}, x_0)$ . Suppose without loss of generality that  $x_0 \in V_1$ . Then an easy induction argument shows that  $x_{2i} \in V_1$  and  $x_{2i+1} \in V_2$  for  $0 = 1, \dots, k$ . But then the edge between  $x_{2k}$  and  $x_0$  means that there is an edge between two nodes in  $V_1$ , and this gives a contradiction.

Conversely, if  $G(V, E)$  has no odd-length cycles, we can partition the vertices in  $V$  into two sets by starting at an arbitrary vertex  $x_0$ , putting it in  $V_0$ , putting all the vertices you get to in one step from  $x_0$  into  $V_1$ , putting all the vertices you can get to in exactly 2 steps into  $V_0$ , etc. It's not hard to prove that this construction works if  $G$  has no odd-length cycles (and fails if it has one).

This construction also gives us a polynomial-time algorithm for checking if a graph is bipartite.

[You're not responsible for this for the prelim/final.]
