### Introduction to Compilers Radu Rugina

#### Lecture 28: Loop Optimizations 07 Apr 06

## Loop Invariant Code

- Idea: if a computation produces same result in all loop iterations, move it out of the loop
- Example: 

```
for (i=0; i<10; i++)  
    a[i] = 10*i + x*x;
```
- Expression  $x*x$  produces the same result in each iteration; move it of the loop:

```
t = x*x;  
for (i=0; i<10; i++)  
    a[i] = 10*i + t;
```

CS 412/413 Spring 2006

Introduction to Compilers

2

## Loop Invariant Computation

- An instruction  $a = b \text{ OP } c$  is **loop-invariant** if each operand is:
  - Constant, or
  - Has all definitions outside the loop, or
  - Has exactly one definition, and that is a loop-invariant computation
- Reaching definitions analysis computes all the definitions of  $x$  and  $y$  which may reach  $t = x \text{ OP } y$

CS 412/413 Spring 2006

Introduction to Compilers

3

## Code Motion

- Suppose  $a = b \text{ OP } c$  is loop-invariant
- We want to hoist it out of the loop
- Code motion of a definition  $d: a = b \text{ OP } c$  in pre-header is valid if:
  1. Definition  $d$  dominates the nodes after the loop exit where  $a$  is live
  2. There is no other definition of  $a$  in loop
  3. All uses of  $a$  in the loop can only be reached from  $d$  otherwise, just move the computation  $b \text{ OP } c$

CS 412/413 Spring 2006

Introduction to Compilers

4

## Other Issues

- **Preserve dependencies** between loop-invariant instructions when hoisting code out of the loop

```
for (i=0; i<N; i++) {  
    x = y+z;          x = y+z;  
    t = x*x;          t = x*x;  
    a[i] = 10*i + x*x;  for(i=0; i<N; i++)  
    }                  a[i] = 10*i + t;
```

- **Nested loops:** apply loop invariant code motion algorithm multiple times

```
for (i=0; i<N; i++)          t1 = x*x;  
    for (j=0; j<M; j++)      for (i=0; i<N; i++) {  
        a[i][j] = x*x + 10*i + t2 = t1+ 10*i;  
                          100*j;      for (j=0; j<M; j++)  
        }                  a[i][j] = t2 + 100*j;
```

5

## Induction Variables

- An **induction variable** is a variable in a loop, whose value is linear with respect to the loop iteration number

$$v = f(i)$$
$$f(i) = c*i + d$$

- **Observation:** linear combinations of linear functions are linear functions
  - Consequence: linear combinations of induction variables are induction variables

CS 412/413 Spring 2006

Introduction to Compilers

6

## Induction Variables

- Two categories of induction variables
- Basic induction variables:** only incremented in loop body  
 $i = i + c$   
 where  $c$  is a constant (positive or negative)
- Derived induction variables:** expressed as a linear function of an induction variable  
 $k = c*j + d$   
 where:
  - either  $j$  is basic induction variable
  - or  $j$  is derived induction variable relative to  $i$  and:
    1. No definition of  $j$  outside the loop reaches definition of  $k$
    2.  $i$  is not defined between the definitions of  $j$  and  $k$

CS 412/413 Spring 2006

Introduction to Compilers

7

## Families of Induction Variables

- Each basic induction variable defines a family of induction variables
  - Each variable in the family of  $i$  is a linear function of  $i$
- A variable  $k$  is in the family of basic variable  $i$  if:
  1.  $k = i$  (the basic variable itself)
  2.  $k$  is a linear function of other variables in the family of  $i$ :  
 $k = c*j + d$ , where  $j \in \text{Family}(i)$
- A triple  $\langle i, a, b \rangle$  denotes an induction variable  $k$  in the family of  $i$  such that:  $k = i*a + b$ 
  - Triple for basic variable  $i$  is  $\langle i, 1, 0 \rangle$

CS 412/413 Spring 2006

Introduction to Compilers

8

## Dataflow Analysis Formulation

- Detection of induction variables:** can formulate problem using the dataflow analysis framework
  - Analyze loop body sub-graph, except the back edge
  - Analysis is similar to constant folding
- Dataflow information:** a function  $F$  that assigns a triple to each variable:
  - $F(k) = \langle i, a, b \rangle$ , if  $k$  is an induction variable in family of  $i$
  - $F(k) = \perp$ :  $k$  is not an induction variable
  - $F(k) = \top$ : don't know if  $k$  is an induction variable

CS 412/413 Spring 2006

Introduction to Compilers

9

## Dataflow Analysis Formulation

- Meet operation:** if  $F1$  and  $F2$  are two functions, then:
 
$$(F1 \sqcap F2)(v) = \begin{cases} \langle i, a, b \rangle & \text{if } F1(k)=F2(k)=\langle i, a, b \rangle \\ \perp & \text{otherwise} \end{cases}$$
 (in other words, use a flat lattice)
- Initialization:**
  - Detect all basic induction variables
  - At loop header:  $F(i) = \langle i, 1, 0 \rangle$  for each basic variable  $i$
- Transfer function:**
  - consider  $F$  is information before node  $n$
  - Compute information  $F'$  after  $n$

CS 412/413 Spring 2006

Introduction to Compilers

10

## Dataflow Analysis Formulation

- For a definition  $k = j + c$ , where  $k$  is not basic induction variable  
 $F'(v) = \langle i, a, b + c \rangle$ , if  $v = k$  and  $F(j) = \langle i, a, b \rangle$   
 $F'(v) = F(v)$ , otherwise
- For a definition  $k = j * c$ , where  $k$  is not basic induction variable  
 $F'(v) = \langle i, a * c, b * c \rangle$ , if  $v = k$  and  $F(j) = \langle i, a, b \rangle$   
 $F'(v) = F(v)$ , otherwise
- For any other instruction and any variable  $k$  in  $\text{def}[n]$ :  
 $F'(v) = \perp$ , if  $F(v) = \langle k, a, b \rangle$   
 $F'(v) = F(v)$ , otherwise

CS 412/413 Spring 2006

Introduction to Compilers

11

## Strength Reduction

- Basic idea:** replace expensive operations (multiplications) with cheaper ones (additions) in definitions of induction variables

```

while (i < 10) {
  j = ...; // <i, 3, 1>
  a[j] = a[j] - 2;
  i = i + 2;
}

```

```

s = 3*i + 1;
while (i < 10) {
  j = s;
  a[j] = a[j] - 2;
  i = i + 2;
  s = s + 6;
}

```

- Benefit:** cheaper to compute  $s = s + 6$  than  $j = 3*i$ 
  - $s = s + 6$  requires an addition
  - $j = 3*i$  requires a multiplication

CS 412/413 Spring 2006

Introduction to Compilers

12

## General Algorithm

- Algorithm:

For each induction variable  $j$  with triple  $\langle i, a, b \rangle$  whose definition involves multiplication:

1. create a new variable  $s$
2. replace definition of  $j$  with  $j=s$
3. immediately after  $i=i+c$ , insert  $s = s+a*c$  (here  $a*c$  is constant)
4. insert  $s = a*i+b$  into preheader

- Correctness:

this transformation maintains the invariant that  $s = a*i+b$

CS 412/413 Spring 2006

Introduction to Compilers

13

## Strength Reduction

- Gives opportunities for copy propagation, dead code elimination

```
s = 3*i+1;
while (i<10) {
  j = s;
  a[j] = a[j] -2;
  i = i+2;
  s = s+6;
}
```

```
s = 3*i+1;
while (i<10) {
  a[s] = a[s] -2;
  i = i+2;
  s = s+6;
}
```

CS 412/413 Spring 2006

Introduction to Compilers

14

## Induction Variable Elimination

- Idea: eliminate each basic induction variable whose only uses are in loop test conditions and in their own definitions  $i = i+c$ 
  - rewrite loop test to eliminate induction variable

```
s = 3*i+1;
while (i<10) {
  a[s] = a[s] -2;
  i = i+2;
  s = s+6;
}
```

- When are induction variables used only in loop tests?
  - Usually, after strength reduction
  - Use algorithm from strength reduction even if definitions of induction variables don't involve multiplications

CS 412/413 Spring 2006

Introduction to Compilers

15

## Induction Variable Elimination

- Rewrite test condition using derived induction variables
- Remove definition of basic induction variables (if not used after the loop)

```
s = 3*i+1;
while (i<10) {
  a[s] = a[s] -2;
  i = i+2;
  s = s+6;
}
```

```
s = 3*i+1;
while (s<31) {
  a[s] = a[s] -2;
  s = s+6;
}
```

CS 412/413 Spring 2006

Introduction to Compilers

16

## Induction Variable Elimination

For each basic induction variable  $i$  whose only uses are

- The test condition  $i < u$
- The definition of  $i$ :  $i = i + c$

Take a derived induction variable  $k$  in its family, with triple  $\langle i, c, d \rangle$

Replace test condition  $i < u$  with  $k < c*u+d$

Remove definition  $i = i+c$  if  $i$  is not live on loop exit

CS 412/413 Spring 2006

Introduction to Compilers

17

## Where We Are

- Defined dataflow analysis framework
- Used it for several analyses
  - Live variables
  - Available expressions
  - Reaching definitions
  - Constant folding
- Loop transformations
  - Loop invariant code motion
  - Induction variables
- Next:
  - Pointer alias analysis

CS 412/413 Spring 2006

Introduction to Compilers

18

## Pointer Alias Analysis

- Most languages use variables containing addresses
  - E.g. pointers (C,C++), references (Java), call-by-reference parameters (Pascal, C++, Fortran)
- **Pointer aliases:** multiple names for the same memory location, which occur when dereferencing variables that hold memory addresses
- **Problem:**
  - Don't know what variables read and written by accesses via pointer aliases (e.g. \*p=y, x=\*p, p.f=y, x=p.f, etc.)
  - Need to know accessed variables to compute dataflow information after each instruction

CS 412/413 Spring 2006

Introduction to Compilers

19

## Pointer Alias Analysis

- **Worst case scenarios**
  - \*p = y may write any memory location
  - x = \*p may read any memory location
- Such assumptions may affect the precision of other analyses
- **Example1:** Live variables  
before any instruction x = \*p, all the variables may be live
- **Example 2:** Constant folding  
a = 1; b = 2; \*p = 0; c = a+b;  
c = 3 at the end of code only if \*p is not an alias for a or b!
- **Conclusion:** precision of result for all other analyses depends on the amount of alias information available
  - hence, it is a fundamental analysis

CS 412/413 Spring 2006

Introduction to Compilers

20

## Alias Analysis Problem

- **Goal:** for each variable v that may hold an address, compute the set  $\text{Ptr}(v)$  of possible targets of v
  - $\text{Ptr}(v)$  is a set of variables (or objects)
  - $\text{Ptr}(v)$  includes stack- and heap-allocated variables (objects)
- Is a "may" analysis: if  $x \in \text{Ptr}(v)$ , then v may hold the address of x in some execution of the program
- **No alias information:** for each variable v,  $\text{Ptr}(v) = V$ , where V is the set of all variables in the program

CS 412/413 Spring 2006

Introduction to Compilers

21

## Simple Alias Analyses

- **Address-taken analysis:**
  - Consider AT = set of variables whose addresses are taken
  - Then,  $\text{Ptr}(v) = \text{AT}$ , for each pointer variable v
  - Addresses of heap variables are always taken at allocation sites (e.g. x = new int[2], x=malloc(8))
  - Hence AT includes all heap variables
- **Type-based alias analysis:**
  - If v is a pointer (or reference) to type T, then  $\text{Ptr}(v)$  is the set of all variables of type T
  - Example: p.f and q.f can be aliases only if p and q are references to objects of the same type
  - Works only for strongly-typed languages

CS 412/413 Spring 2006

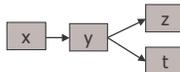

Introduction to Compilers

22

## Dataflow Alias Analysis

- **Dataflow analysis:** for each variable v, compute points-to set  $\text{Ptr}(v)$  at each program point
- **Dataflow information:** set  $\text{Ptr}(v)$  for each variable v
  - Can be represented as a graph  $G \subseteq 2^{V \times V}$
  - Nodes = V (program variables)
  - There is an edge  $v \rightarrow u$  if  $u \in \text{Ptr}(v)$

$\text{Ptr}(x) = \{y\}$   
 $\text{Ptr}(y) = \{z,t\}$

CS 412/413 Spring 2006

Introduction to Compilers

23

## Dataflow Alias Analysis

- **Dataflow Lattice:**  $(2^{V \times V}, \supseteq)$ 
  - $V \times V$  is set of all possible points-to relations
  - "may" analysis: top element is  $\emptyset$ , meet operation is  $\cup$
- **Transfer functions:** use standard dataflow transfer functions:  
 $\text{out}[I] = (\text{in}[I] - \text{kill}[I]) \cup \text{gen}[I]$ 

p = addr q	kill[I] = {p} x V	gen[I] = {(p,q)}
p = q	kill[I] = {p} x V	gen[I] = {p} x Ptr(q)
p = *q	kill[I] = {p} x V	gen[I] = {p} x Ptr(Ptr(q))
*p = q	kill[I] = ...	gen[I] = Ptr(p) x Ptr(q)

For all other instruction,  $\text{kill}[I] = \{\}$ ,  $\text{gen}[I] = \{\}$
- Transfer functions are monotonic, but not distributive!

CS 412/413 Spring 2006

Introduction to Compilers

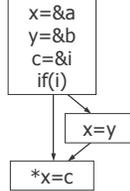

24

## Alias Analysis Example

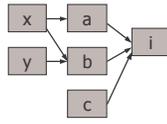

### Program

```
x=&a;
y=&b;
c=&i;
if(i) x=y;
*x=C;
```

### CFG

### Points-to Graph (at the end of program)

CS 412/413 Spring 2006

Introduction to Compilers

25

## Alias Analysis Uses

- Once alias information is available, use it in other dataflow analyses

- Example: Live variable analysis

Use alias information to compute use[I] and def[I] for load and store statements:

$x = *y$	$use[n] = \{y\} \cup Ptr(y)$	$def[n] = \{x\}$
$*x = y$	$use[n] = \{x, y\}$	$def[n] = Ptr(x)$

CS 412/413 Spring 2006
